<ul> <li>16-1 Estimating Latency </li> <li>Goal: <ul> <li>given information about events and their handlers</li> <li> estimate response times</li> <li> or devise scheduling to insure that deadlines are met. </li> </ul> </li> <li>Definitions: Latency [of an interrupt handler or dæmon task to an event]: Time from event occurrence to start of its handler or dæmon task. Response time [of interrupt handler or dæmon task to an event]: Time from event occurrence to response. In class response assumed to be generated at completion of event's handler. Let an event occur at t<sub>1</sub>, its handler start at t<sub>2</sub> and finish at t<sub>3</sub> then the latency is t<sub>2</sub> - t<sub>1</sub> and response time t<sub>3</sub> - t<sub>1</sub>. Run time [of interrupt handler or dæmon task]: The time needed to run<sup>1</sup> on an unloaded system. Actual run time [of interrupt handler or dæmon task]: The time needed to run in a particular situation (considering other CPU activity, etc.).</li></ul>	16-1	<ul> <li>16-2</li> <li>Worst-case latency [of an int. handler or dæmon task to an ev The longest possible latency given constraints on when a can occur, etc.</li> <li>Worst-case response time [of an int. handler or dæmon task event]: The longest possible response time given constraints on events can occur, etc.</li> <li>Worst-case run time [of an int. handler or dæmon task to an e The longest possible actual run time given constraints on events can occur, etc.</li> <li>For a particular event, response time is always latency plus actu time.</li> <li>However, the worst-case response time is not necessarily the wor latency plus the worst-case actual run-time.</li> <li>Unless otherwise stated, all latencies, actual run times, and re times are worst case.</li> </ul>	rent]: events to an when event]: when ial run st-case
<ul> <li><sup>1</sup> For handlers (which run something like operating system subroutines), run time is total run time. For daemons (which are tasks managed like any other tasks the OS is running) it's the amount of run time needed to generate a response. After the response the daemon will wait for another event, in contrast to a handler which actually finishes execution. At a subsequent event a waiting daemon moves from the wait state (if the event is handled by a daemon), while a "fresh" call to a handler is made (if the event is handled by a daemon).</li> <li><b>16-1</b> EE 4770 Lecture Transparency. Formatted 13:27, 23 December 1997 from klit6.</li> <li><b>16-3</b> Classes of problems:         <ul> <li>One-shot.</li> </ul> </li> </ul>	16-1	16-2 EE 4770 Lecture Transparency. Formatted 13:27, 23 December 1997 from Islii 6. 16-4 Events, Event Types, and Interrupts An event is some occurrence in the process.	16-2
<ul> <li>One-shot. Assume that each event can occur at most once.</li> <li>Periodic exhaustive. Events occur periodically, solution found exhaustively.</li> <li>Periodic statistical. Events occur periodically, solution found using statistical methods.</li> </ul>		<ul> <li>An event is some occurrence in the process.</li> <li>For example, temperature exceeding a threshold.</li> <li>(This is the definition used throughout the semester.)</li> <li>An event type is a kind of event.</li> <li>As a result of an event, which is of a certain event type, an intis requested; as a result a handler is run.</li> <li>For example, consider a system where CDT marks trigger interesting the coded displacement transducer.</li> <li>Event: at t = 30 the clock mark passes under the mark of the coded displacement transducer.</li> <li>Interrupt: the interruption caused by this event.</li> <li>Handler: the CDT code that is run for this interrupt.</li> <li>Each of these four terms has a different meaning, for brevit sometimes will be used interchangeably.</li> </ul>	rrupts: of the reader

<sup>16-3</sup> 

16-7

Timing Estimation Problem:

Given:

Archetypical Problems

• Handlers and tasks for events. How long these will run.

Handlers and tasks generate a *response* by the end of their run.

• Events. When the events can occur.

16-5

16-6

# Trivial Example Problem

A RTS must react to a single event. Exactly 5  $\mu$ s after the event occurs the NMI-request line will be asserted. (The delay is due to a slow sensor response.) The handler for this event requires 100  $\mu$ s to generate a response to the event. The following are the timings of other system functions: context save, 100 ns; task switch, 50  $\mu$ s; scheduler run time, 100  $\mu$ s; worst-case instruc-tion completion 50  $\mu$ s; we require and impute address are instruction completion, 50 ns; masking and jump to address specified in IVT, 20 ns. Find the worst-case response time.

Pure Weak Priority, One-Shot Example Problem		Strong and Weak Priority, One-Shot Events
Find the worst-case response time for all events in a system	using	This covers two possible sets of conditions:
pure-weak-priority interrupts and one-shot events. The e and interrupt handlers are described below.	events	Interrupts:
Event Priority Run Time		• Responses are generated by interrupt handlers.
$\begin{array}{ccc} A & 3 & 10\mu\mathrm{s} \\ B & 7 & 15\mu\mathrm{s} \end{array}$		$\diamond$ An IRQ input can be used by any number of events.
$C$ 1 $8 \mu s$		$\Diamond$ The interrupt to service determined by polling sequence
Solution:		using a different sequence for each strong priority level.
Latency for A: $t_h(B) + t_h(C) = 23 \mu s.$		• Interrupts can only be masked by other interrupts.
Response time of A is $t_h(B) + t_h(C) + t_h(A) = 33 \mu s.$		There are no tasks or other unrelated activities which can mask interrupts.
		• Only handler run time is significant.
Latency for B is $t_h(A) = 10 \mu\text{s}$ .		Tasks:
Response time of B is $t_h(A) + t_h(B) = 25 \mu s.$		
Latency for C: $t_h(A) + t_h(B) = 25 \mu s.$		Responses are generated by tasks, exactly one task per event.
Response time of C is $t_h(A) + t_h(B) + t_h(C) = 33 \mu s.$		<ul> <li>♦ Scheduling done in two rounds, both use priority scheduling.</li> <li>♦ The first round is task-preemptive, the second round is non-task-</li> </ul>
Notes:		preemptive.
A and $C$ cannot simultaneously have worst-case response times Highest weak priority level <u>does not</u> guarantee lowest response		• Only tasks specified in the problem need be considered. (No other tasks will preempt or be selected before the tasks
(This will be seen in an example below.)	time.	• The quantum is infinite.
		Items that differ from the pure-weak-priority case are shown in slanted type with diamonds for bullets.

Interrupt Latency of Strong and Weak Priority, One-Shot	Events	Strong and Weak Priority, One-Shot Example Problem
Let		Find the worst-case response time for all events in a system using strong and weak priority interrupts and one-shot events. The
${\mathcal E}$ be a set of event types		events and interrupt handlers are described below.
$(e.g., \mathcal{E} = \{$ button3, tempAlarm, eventX, 3, $A\}),$		Event Strong Weak Run Priority Priority Time
all events in $\mathcal{E}$ be one shot,		A 3 1 10 µs
$t_h(e)$ be the run time of the handler for event $e \in \mathcal{E}$ ,		$\begin{bmatrix} B & 2 & 3 & 15\mu s \\ C & 2 & 2 & 8\mu s \end{bmatrix}$
$p_1(e)$ be the strong priority level of the handler for event $e \in \mathcal{E}$	,	$ \begin{array}{cccccccccccccccccccccccccccccccccccc$
$p_2(e)$ be weak priority level of handler for $e \in \mathcal{E}$ .		$F$ 1 1 $2\mu$ s
Then worst-case latency for event $e \in \mathcal{E}$ is		Solution:
$\sum t_k(i) + \sum t_k(i) + \max t_k(i)$		Event A
$\sum_{\substack{i \in \mathcal{E} \\ p_1(i) > p_1(e)}} t_h(i) + \sum_{\substack{p_1(i) = p_1(e) \\ p_1(i) > p_2(e)}} t_h(i) + \max_{\substack{i \in \mathcal{E} \\ p_1(i) = p_1(e) \\ p_2(i) < p_2(e)}} t_h(i).$		Event order: A occurs any time.
$\begin{array}{cccc} p_1(i) > p_1(e) & p_1(e) & p_2(i) < p_2(e) \\ & p_2(i) > p_2(e) \end{array}$		Latency for $A: 0\mu s.$
In words:		Response time of A is $t_h(A) = 10 \mu s.$
Sum of the run times of		
$\ldots$ all higher strong-priority and weak-priority handlers		Event B
plus longest run time of		Possible event order: $D, B, A$ .
the lower weak-priority handlers		Latency for B is $t_l(B) = t_h(A) + t_h(D) = 60 \mu s.$
that are at the same strong priority level as $e$ .		Response time of B is $t_l(B) + t_h(B) = 75 \mu s.$
This worst-case latency is encountered by $e$ if:		Event $C$
The longest-run-time handler at the same strong priority level.		Possible event order: $D, C, B, A$ .
$\ldots$ starts to run just before $e$		Latency for C: $t_l(C) = t_h(A) + t_h(B) + t_h(D) = 75 \mu \text{s}.$
$\ldots$ and all higher priority interrupts occur before $e$ 's handler sta	arts.	Response time of C is $t_l(C) + t_h(C) = 83 \mu s.$

Example, continued.		Example Problem Solution Details	
Event Strong Weak Run Time		Simulator Output Format	
$\begin{array}{c ccc} \hline Priority & Priority & Time \\ \hline A & 3 & 1 & 10\mu s \end{array}$		Output divided into sections divided by lines like:	
$egin{array}{cccccccccccccccccccccccccccccccccccc$		======B Worst-Case Latency and Run Time ====================================	
$D$ 2 1 $50\mu\mathrm{s}.$		Each section demonstrates worst-case behavior for a different event.	
$E   1   2   1 \mu s. F   1   1   2 \mu s.$		Handler timing given in lines like: Handler for F (1) finished: lat. 99., dur. 2., resp. 101.	
Event $D$		which indicates that occurrence 1 of event $F$ had a latency of 99, actual run time (duration) of 2,	
Possible event order: $B, D, C, A$ .		and a response time of 101.	
Latency for D: $t_l(D) = t_h(A) + t_h(B) + t_h(C) = 33 \mu s.$		This timing information is shown for all events, only a few of which suffer worst-case delays. (The event suffering worst-case delays is indicated in the section heading, but watch for multiple occurrence of the same event.)	
Response time of D is $t_l(D) + t_h(D) = 83 \mu s.$		Each section heading is printed at $t = 4 \pmod{1000}$ , the first event in each section occurs at time $t = 5 - \epsilon \pmod{1000}$ and the event suffering worst case latency and response time occurs	
Event $E$		$t \to 0 - \epsilon$ (mod 1000) and the event smering worst case ratency and response time occurs at time $t = 5 \pmod{1000}$ , where $\epsilon$ is a very small time interval.	
Possible event order: $F, E, A, B, C, D$ .		Simulator Output	
		** Time: 4 ====================================	
Latency for E: $t_l(E) = \sum_{e \in \{A, B, C, D, F\}} t_h(e) = 85 \mu s.$		Interrupt D (0) requested. Handler for D (0) starting.	
Response time of E is $t_l(E) + t_h(E) = 86 \mu s.$		** Time: 5 Interrupt B (0) requested. ** Time: 6	
Event $F$		Interrupt A (0) requested. Handler for D (0) preempted.	
Possible event order: $E, F, A, B, C, D$ .		Handler for A (0) starting. ** Time: 16 Handler for A (0) finished: lat. 0, dur. 10, resp. 10	
		Handler for D (0) resumed. ** Time: 65.	
Latency for $F$ : $t_l(F) = \sum_{e \in \{A, B, C, D, E\}} t_h(e) = 84 \mu \text{s}.$		Handler for D (0) finished: lat. 0., dur. 60., resp. 60. Handler for B (0) starting. ** Time: 80.	
Response time of F is $t_l(F) + t_h(F) = 86 \mu s.$		Handler for B (0) finished: lat. 60., dur. 15., resp. 75. ** Time: 1,004

Useful problems based on perturbation of one-shot assumption. These problems solved by adapting one-shot solution procedure. Adapting Solution Instead of using latency formulas (from previous slides) find an ordering of events meeting problem restrictions while resulting in worst-case behavior. Two Perturbations from One-Shot • Timing restrictions on events. • Multiple occurrences of an event type. Timing Restrictions Usually minimum or maximum time between events. $E.g.$ , event $A$ occurs $\geq 12 \mu s$ after $B$ .
16-21 EE 4770 Lecture Transparency. Formatted 13:27, 23 December 1997 from Isli16.	16-21	16-22         EE 4770 Lecture Transparency. Formatted 13:27, 23 December 1997 from Isli16.         16-22
16-23	16-23	16-24 16-24
Multiple Event Occurrences Event may happen several times. Bound on number and timing of occurrences will be given. $E.g.$ , event $A$ occurs $\leq 3$ times $> 5 \mu s$ apart. Multiple Occurrences Notation Subscript used to indicate occurrence. $E.g.$ , $A_1$ , first occurrence of event type $A$ ; $A_2$ second. Handling Multiple Occurrences In class, the handler must be run for each occurrence. $E.g.$ , if $A$ occurs twice $(A_1$ and $A_2),$ handler for $A$ must be run twice even if $A_2$ occurs before handler for $A_1$ runs.		$\begin{array}{ c c c c c c c c c c c c c c c c c c c$

16-26

Example, continued.	Example, continued.
$ \begin{array}{c ccccc} \hline \text{Event} & \text{Strong} & \text{Weak} & \text{Run} & \text{Event} \\ \hline & & & & \\ \hline Priority & Priority & Time & Occurrences \\ \hline \hline A & 3 & 1 & 10\mu s & Occurs once, any time. \\ \hline B & 2 & 3 & 15\mu s & Occurs twice, any times. \\ \hline C & 2 & 2 & 8\mu s & Occurs once, 45 to 50\mu s after event A. \\ \hline D & 2 & 1 & 50\mu s & Occurs once, any time. \\ \hline E & 1 & 2 & 1\mu s & Occurs three times, with > 100\mu s \text{separ} \\ \hline F & 1 & 1 & 2\mu s & Occurs once. \\ \hline \end{array} $	$ \begin{array}{c c c c c c c c c c c c c c c c c c c $
Event $C$	Event $E$
C only occurs after event $A$ so:	Both $A$ and $C$ can occur during $E$ 's latency.
Possible event order: $D, C, B_1, B_2$ .	Possible event order: $F, E, A, B_1, B_2, D, C$
Latency for C: $t_l(C) = 2t_h(B) + t_h(D) = 80 \mu\text{s}.$	Latency for E: $t_l(E) = \sum_{e \in \{A, B_1, B_2, C, D, F\}} t_h(e) = 100 \mu s.$
Response time of C is $t_l(C) + t_h(C) = 88 \mu\text{s}.$	$e \in \{A, B_1, B_2, C, D, F\}$ Response time of $E$ is $t_l(E) + t_h(E) = 101 \mu\text{s}.$
Event D.	Event $F$
${\cal C}$ and ${\cal A}$ cannot both occur within $D$ 's latency period.	E is second occurrence is after $F$ starts.
Possible event order: $B_1$ , $D$ , $A$ , $B_2$ .	Possible event order: $E_1$ , $F$ , $A$ , $B_1$ , $B_2$ , $D$ , $C$
Latency for D: $t_l(D) = t_h(A) + 2t_h(B) = 40 \mu s.$	
Response time of D is $t_l(D) + t_h(D) = 90 \mu s.$	Latency for F: $t_l(F) = \sum_{e \in \{A, B_1, B_2, C, D, E\}} t_h(e) = 99 \mu\text{s.}$
	Response time of F is $t_l(F) + t_h(F) = 101 \mu s.$

16-32Periodic EventsAn event type is said to be periodic ifthe time between occurrences is fixedthe time of occurrences (phase) is arbitrary.The period is the time between occurrences. $t_b(X)$ will denote the period of event type X.(The b is for between.)ExampleLet $t_b(A) = 10$ s, where A is an event type.Then A might occur at $t/s = 10, 20, 30, \ldots$ Or A might occur at $t/s = 12, 22, 32, \ldots$

16-37	16-37 16-38 16-38
WC Run Using Average Number of Interruptions	Important Quantity in Average Method: Loading Factor
Ignoring fact that $n$ is an integer	Consider actual run time equation:
let $n = t_a(B)/t_b(A)$ .	$t_a(B) = \frac{t_h(B)}{1 - \frac{t_h(A)}{t_h(A)}}.$
This average contains unknown value, $t_a(B)$ .	Average $n = t_b(A)/t_b(B)$ not explicit.
Solving for $t_a(B)$ yields $t_a(B) = \frac{t_h(B)}{1 - \frac{t_h(A)}{t_h(A)}}$ .	
$1 - \frac{1}{t_b(A)}$	But $1 - \frac{t_h(A)}{t_b(A)}$ is.
Average Method on Illustration	So $1 - \frac{t_h(A)}{t_b(A)}$ will be used instead of average <i>n</i> .
Substituting yields $t_a(B) = 675 \mu s.$	$1 - \frac{t_h(A)}{t_b(A)}$ is example of loading factor.
Difference, $750 \mu s - 675 \mu s = 75 \mu s$ , too big to ignore	
$\dots$ but as $n$ increases the difference drops.	Intuitive Definition of Loading Factor
	Fraction of CPU time that A leaves for B.
	<i>B</i> 's run time computed for slower CPU using loading factor.
	First definitions, then details of the statistical method.

Definitions	Load Set
Load (noun) [that a handler places on system]	Let $Y$ denote an event.
The load of a periodic event's handler is	The load set for $Y$ is
*	$\ldots$ the set of events that load Y.
$l = t_h/t_b, \dots$	Loading Factor
$\ldots$ where $t_h$ is run time of handler $\ldots$	Let $Y$ denote an event
$\dots$ and $t_b$ is event's period.	Let Y denote an event and $\mathcal{X}$ be the load set for Y.
In words: fraction of CPU time needed by handler.	Then the <i>loading factor</i> for $Y$ 's handler is
A system will be overloaded if the sum of all loads is greater than one.	
Load (verb)	$l_f(Y) = 1 - \sum_{e \in \mathcal{X}} \frac{t_h(e)}{t_b(e)}.$
Event $X$ is said to load event $Y$	In words: $Y$ 's loading factor is fraction of CPU time
$\dots$ if strong priority of X is higher than $Y \dots$	$\dots$ available to Y's handler $\dots$ $\dots$ after accounting for $\mathcal{X}$ , the load set.
and $\theta_t t_h(X) < t_h(Y),$	
	Loaded Duration
where $\theta_l$ is a constant called the <i>loading threshold</i> .	Let Y denote an event with loading factor $l_f(Y)$ .
Loading Threshold Values	Then the <i>loaded duration</i> of event $Y$ 's handler is
Higher values give more precise answers.	$t_h'(Y) = \frac{t_h(Y)}{l_f(Y)}.$
Unless stated otherwise $\theta_l = 50$ .	
	<u>Note</u> : the actual duration, $t_a(Y)$ , can be longer.

General Solution Technique		Statistical-Latency-Estimation Example Problem	
Start at the highest strong-priority level.		A RTS has three event types, all periodic. Their period, priority, and	
For all events in a strong-priority level:		the run time of their handlers is listed in the table below. Find the latency and response time for each event.	ł
• Find the loading factor, compute the loaded duration.		Event Strong Period Handler Run	
• Exhaustively compute the actual duration (consider only lo priority events which do not load the event being considere		$\begin{array}{c ccc} \hline \text{Name} & \text{Priority} & t_b & \text{Time, } t_h \\ \hline \hline A & 3 & 10\mu\text{s} & 0.5\mu\text{s} \\ B & 2 & 50\text{ms} & 37\mu\text{s} \\ \end{array}$	
• Exhaustively compute the latency.		$C$ 1 1s $40 \mu s$	
• Exhaustively compute the response time.		Solution:	
Repeat for the next lower strong-priority level or finish if at the lo	owest	• Event $A$	
strong priority.		Latency, $t_l(A) = 0  \mu s.$	
		Response time, $t_r(A) = t_l(A) + t_h(A) = 0.5 \mu s.$	
		• Event B	
		$\frac{t_h(B)}{t_h(A)} = 74 > \theta_l = 50, \text{ therefore } A \text{ loads } B.$	
		Loading factor for B is $l_f(B) = 1 - \frac{t_h(A)}{t_b(A)} = 0.95.$	
		Loaded duration: $t'_h(B) = \frac{t_h(B)}{l_f(B)} = 38.95 \mu \text{s.}$	
		Latency, $t_l(B) = t_h(A) = 0.5 \mu \text{s}.$	
		Response time, $t_r(B) = t_l(B) + t'_h(B) = 39.45 \mu s.$

Another Statistical Latency Estimation Example Problem	Example, continued.
A RTS must react to six event types. The names of the event types, their occurrence times, the priorities of their respective inter- rupts, and the run time of their handlers is listed in the table below. For each event type find the latency, duration, and re- sponse time. Also find the total system load.	$ \begin{array}{c ccccc} \mbox{Event Strong Weak Handler Occurrence} \\ \hline Name Pri. Pri. Run Time \\ \hline A & 4 & 2 & 3\mu s & \mbox{Periodic, } t_b(A) = 20\mu s. \\ \hline B & 4 & 1 & 2\mu s & \mbox{From 7}\mu s \mbox{ to } 13\mu s \mbox{ after event } A, \mbox{ if at all.} \\ \hline C & 3 & 1 & \mbox{700}\mu s & \mbox{Periodic, } t_b(C) = 27\mbox{ms.} \end{array} $
$ \begin{array}{c ccccccccccccccccccccccccccccccccccc$	$ \begin{array}{cccccccccccccccccccccccccccccccccccc$
$D$ At most 2 unresponded events held. $E$ 211 msPeriodic, $t_b(E) = 100 \text{ ms.}$ $F$ 11500 msAnytime after resp. to prev. occur.	Loading: $A, B$ .
Solution:	$\frac{\text{effective}}{t_b(B)} t_b(B) \text{ same as } t_b(A).$
Events A and B	$l_f(C) = 1 - \frac{t_h(A)}{t_b(A)} - \frac{t_h(B)}{t_b(A)} = 0.75.$
From table above, cannot occur at same time.	Actual run time $t_a(C) = \frac{t_h(C)}{l_s(C)} = 933\frac{1}{3}\mu s.$
A possible event sequence: $A$ .	$l_f(\mathbb{C}) = 3$ Event <i>D</i> Run Time
B possible event sequence: $B$ .	Use exhaustive method, note variation in $B$ 's timing.
And so latency: $t_l(A) = t_l(B) = 0 \mu s.$	Possible event sequence: $D, B_1, A, B_2$ .
Response time: $t_r(A) = t_a(A) = 3 \mu s.$	$t_a(D) = t_h(D) + 2t_h(B) + t_h(A) = 18\mu s.$
Response time: $t_r(B) = t_a(B) = 2 \mu s.$

16-47

16-47

16-48

Possible event sequence: C\*,  $D_1$ ,  $D_2$ ,  $B_1$ ,  $A_1$ ,  $B_2$ ,  $A_2$ .

Response time  $t_r(D) = t_a(C) + 2(t_h(D) + t_h(A) + t_h(B)) = 965.33 \,\mu\text{s}.$ 

Example, continued.

Event Name	Strong Pri.	Weak Pri.	Handler Run Time	Occurrence
A	4	2	$3 \mu s$	Periodic, $t_b(A) = 20 \mu s.$
B	4	1	$2\mu s$	From $7 \mu \text{s}$ to $13 \mu \text{s}$ after event A, if at all.
C	3	1	$700  \mu s$	Periodic, $t_b(C) = 27 \mathrm{ms.}$
D	3	2	$11 \mu s$	No more than 3 times in any 1 ms interval.
D				At most 2 unresponded events held.
E	2	1	$1\mathrm{ms}$	Periodic, $t_b(E) = 100 \mathrm{ms}.$
F	1	1	$500 \mathrm{ms}$	Anytime after resp. to prev. occur.

Event E

Loaded by A, B, and D:

$$l_f(E) = 1 - \frac{t_h(A)}{t_b(A)} - \frac{t_h(B)}{t_b(B)} - \frac{t_h(D)}{t_b(D)} = 0.717.$$

Worst-case latency includes

 $\ldots$ time for  $C \ldots$ 

 $\dots$  plus time for *D*'s waiting after *C* finishes...

 $t_l(E) = 3t_h(D) + 3t_h(A) + 2t_h(B) + t_a(C) = 979.33 \,\mu s.$ 

Actual duration is similar, except E occurs before C.

$$t_a(E) = \frac{t_h(E)}{l_f(E)} + t_a(C) + 3t_a(D) + 3t_a(A) + 2t_a(B) = 2.374 \,\mathrm{ms}.$$

Response time must not count C twice:

$$t_r(E) = t_l(E) + \frac{t_h(E)}{l_f(E)} = 2.374 \,\mathrm{ms}$$

#### Example Problem Solution Details

EE 4770 Lecture Transparency, Formatted 13:27, 23 December 1997 from Isli16.

### Simulator Output Format

Output shows worst-case scenarios for some events.

As with simulator output appearing above, latency and response times shown are only worst case for a few events, see title at the head of each run.

Events in a handler's load set are not shown while a handler is running. For example, C is loaded by A and B, so while C is running occurrences of A and B are not shown.

Just before a handler starts a message is printed for each active event in its load set, indicating that fore a handler starts a message is printed for each active event in its load set, indicating that those events will be ignored (and the run time of the handler is computed using the loading factor), for example, "Event A simulated using handler load." If the event is already being ignored no message is printed. Similarly, before a handler starts a message is printed for each event which will no longer be ignored. For example, "Normal simulation of A resuming." Sometimes both messages are printed (the software is not yet polished), use the second message.

Loaded Event Handlers Handler for D (0) starting, time remaining 11 Handler for D (0) starting, time remaining 11 \*\* Time: 1,000. Interrupt A (0) requested. Handler for D (0) preempted. Handler for A (0) starting, time remaining 3 \*\* Time: 1,000 Interrupt C (0) requested. \*\* Time: 1,000. \*\* Time: 1,000. Interrupt D (1) requested. \*\* Time: 1,003. Handler for A (0) fnished: latency 0. + duration 3. = response time 3. Handler for D (0) resumed, time remaining 11... \*\* Time: 1,007 Interrupt B (0) requested. Handler for D (0) represpted. Handler for B (0) starting, time remaining 2 \*\* Time: 1,009 Handler for B (0) finished: latency 0 + duration 2 = response time 2  $\begin{array}{l} \mbox{latency 0 + duration 2 = response time 2} \\ \mbox{Handler for D (0) resumed, time remaining 7..} \end{array}$ \*\* Time: 1,016. Handler for D (0) finished: latency 0. + duration 16. = response time 16.

EE 4770 Lecture Transparency. Formatted 13:27, 23 December 1997 from lsli16.

16-50

16-49

Example, continued.

Event Name	Strong Pri.	Weak Pri.	Handler Run Time	Occurrence
Α	4	2	$3\mu s$	Periodic, $t_b(A) = 20 \mu s.$
B	4	1	$2 \mu s$	From $7 \mu s$ to $13 \mu s$ after event A, if at all.
C	3	1	$700  \mu s$	Periodic, $t_b(C) = 27 \mathrm{ms.}$
D	3	2	$11  \mu s$	No more than 3 times in any 1 ms interval.
D				At most 2 unresponded events held.
E	2	1	$1\mathrm{ms}$	Periodic, $t_b(E) = 100 \text{ ms.}$
F	1	1	$500\mathrm{ms}$	Anytime after resp. to prev. occur.

### Event F

All other events load F:

$$l_f(F) = 1 - \sum_{e \in \{A, B, C, D, E\}} \frac{t_a(e)}{t_b(e)} = 0.681$$

Duration

$$t_a(F) = \frac{t_h(F)}{l_f(F)} = 734.1 \,\mathrm{ms}.$$

Latency of F is the same as response time of E since there is only one interrupt at strong levels 1 and 2 and since neither interrupt will recur until after handler finishes.

$$t_l(F) = t_r(E) = 2.374 \,\mathrm{ms.}$$

$$t_r(F) = t_l(F) + t_a(F) = 736.5 \,\mathrm{ms.}$$

Because of event F, worst-case load is 1.
